2/1

Compiler structure

token stream Parser syntax tree Semantic analysis (eg, type checking) syntax tree Intermediate code generator low-level IR (eg, canonical trees/tuples) Optimizer low-level IR (eg, canonical trees/tuples) Machine code generator machine code

Potential optimizations:

Source-language (AST):

- constant bounds in
- loops/arraysloop unrolling
- suppressing run-time
- checks
- enable later optimisations
- IR: local and global
 - CSE elimination
 - live variable analysis
 - code hoisting
 - enable later optimisations

Code-generation (machine code):

- register allocation
- instruction scheduling

• peephole optimization

Optimization

Goal: produce fast code

- What is optimality?
- Problems are often hard
- Many are intractable or even undecideable
- Many are NP-complete
- Which optimizations should be used?
- Many optimizations overlap or interact

Optimization

Definition: An optimization is a transformation that is expected to:

- improve the running time of a program
- or decrease its space requirements

The point:

- "improved" code, not "optimal" code (forget "optimum")
- sometimes produces worse code
- range of speedup might be from 1.000001 to xxx

- applicable across broad range of machines
- remove redundant computations
- move evaluation to a less frequently executed place
- specialize some general-purpose code
- find useless code and remove it
- expose opportunities for other optimizations

Machine-dependent transformations

V.Krishna Nandivada (IIT Madras)

A classical distinction

• capitalize on machine-specific properties

- improve mapping from IR onto machine
- replace a costly operation with a cheaper one
- hide latency
- replace sequence of instructions with more powerful one (use "exotic" instructions)

The distinction is not always clear: replace ${\tt multiply}\ with\ {\tt shifts}\ and\ {\tt adds}$

CS6013 - Jan 2020

Optimization

Desirable properties of an optimizing compiler

- code at least as good as an assembler programmer
- stable, robust performance
- architectural strengths fully exploited
- architectural weaknesses fully hidden
- broad, efficient support for language features
- instantaneous compiles

Unfortunately, modern compilers often drop the ball

V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2020 9 / 1

Scope of optimization

Local

(single block)

(global)

(predictability)

- confined to straight-line code
- simplest to analyse
- time frame: '60s to present, particularly now

Intraprocedural

- consider the whole procedure
- What do we need to optimize an entire procedure?
- classical data-flow analysis, dependence analysis
- time frame: '70s to present

Interprocedural

(whole program)

- analyse whole programs
- What do we need to optimize and entire program?
- less information is discernible
- time frame: late '70s to present, particularly now

Optimization

Good compilers are crafted, not assembled

- consistent philosophy
- careful selection of transformations
- thorough application
- coordinate transformations and data structures
- attention to results

Compilers are engineered objects

- minimize running time of compiled code
- minimize compile time
- use reasonable compile-time space

Thus, results are sometimes unexpected

(code, time, space)

(serious problem)

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2020

Optimization

Three considerations arise in applying a transformation:

- safety
- profitability
- opportunity
- We need a clear understanding of these issues
 - the literature often hides them
 - every discussion should list them clearly

Fundamental question Does the transformation change the **results** of executing the code?

yes \Rightarrow don't do it!

no \Rightarrow it is safe

Compile-time analysis

- may be safe in all cases (<u>lo</u>
 analysis may be simple (DAG)
- may require complex reasoning

(loop unrolling)
(DAGs and CSES)
(data-flow analysis)

Profitability

Fundamental question <u>Is there a reasonable expectation that the</u> transformation will be an improvement?

CS6013 - Jan 2020

yes \Rightarrow do it! no \Rightarrow don't do it

Compile-time estimation

- always profitable
- heuristic rules
- compute benefit

V.Krishna Nandivada (IIT Madras)

Opportunity

V.Krishna Nandivada (IIT Madras)

Fundamental question Can we efficiently locate sites for applying the transformation?

CS6013 - Jan 2020

yes \Rightarrow compilation time won't suffer

no \Rightarrow better be highly profitable

Issues

- provides a framework for applying transformation
- systematically find all sites
- update safety information to reflect previous changes
- order of application

(hard)

13/1

Optimization

Successful optimization requires

- test for safety
- profit is *local improvement × executions*
 - \Rightarrow focus on loops:
 - loop unrolling
 - factoring loop invariants
 - strength reduction
- want to minimize side-effects like code growth

Safety: always safe

Profitability: reduces overhead

(instruction cache blowout) (subtle secondary effects)

Opportunity: loops

Unrolling is easy to understand and perform

Example: loop unrolling

(assume 4-word cache line)

```
do i \leftarrow 1, n, 1

do j \leftarrow 1, n, 1

c(i,j) \leftarrow 0

do k \leftarrow 1, n, 4

c(i,j) \leftarrow c(i,j) + a(i,k) * b(k,j)

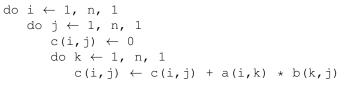

c(i,j) \leftarrow c(i,j) + a(i,k+1) * b(k+1,j)

c(i,j) \leftarrow c(i,j) + a(i,k+2) * b(k+2,j)

c(i,j) \leftarrow c(i,j) + a(i,k+3) * b(k+3,j)
```

- $2n^3$ flops, $\frac{n^3}{4}$ loop increments and branches
- each iteration does 8 loads and 8 flops
- memory traffic is better
 - c(i,j) is reused
 - a(i,k) reference are from cache
 - b(k,j) is problematic

Matrix-matrix multiply

- $2n^3$ flops, n^3 loop increments and branches
- each iteration does 2 loads and 2 flops

This is the most overstudied example in the literature

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2020

10/1

Example: loop unrolling

Matrix-matrix multiply

(to improve traffic on b)

```
do j \leftarrow 1, n, 1
   do i \leftarrow 1, n, 4
      c(i,j) \leftarrow 0
       do k \leftarrow 1, n, 4
          c(i,j) \leftarrow c(i,j) + a(i,k) * b(k,j)
             + a(i,k+1) * b(k+1,j) + a(i,k+2) * b(k+2,j)
             + a(i,k+3) * b(k+3,j)
          c(i+1,j) \leftarrow c(i+1,j) + a(i+1,k) * b(k,j)
             + a(i+1,k+1) * b(k+1,j)
             + a(i+1,k+2) * b(k+2,j)
             + a(i+1,k+3) * b(k+3,j)
          c(i+2,j) \leftarrow c(i+2,j) + a(i+2,k) * b(k,j)
             + a(i+2,k+1) * b(k+1,j)
             + a(i+2,k+2) * b(k+2,j)
             + a(i+2,k+3) * b(k+3,j)
          c(i+3,j) \leftarrow c(i+3,j) + a(i+3,k) * b(k,j)
             + a(i+3,k+1) * b(k+1,j)
             + a(i+3,k+2) * b(k+2,j)
              + a(i+3,k+3) * b(k+3,j)
```

(put it in a register)

Example: loop unrolling

What happened?

- interchanged i and i loops
- unrolled i loop
- fused inner loops
- $2n^3$ flops, $\frac{n^3}{16}$ loop increments and branches
- first assignment does 8 loads and 8 flops
- 2nd through 4th do 4 loads and 8 flops

memory traffic is better

- c(i,j) is reused
- a(i,k) references are from cache
- b(k, j) is reused

(register) (register)

CS6013 - Jan 2020

Loop optimizations: factoring loop-invariants

Loop invariants: expressions constant within loop body Relevant variables: those used to compute and expression

Opportunity:

- identify variables defined in body of loop (LoopDef)
- 2 loop invariants have no relevant variables in *LoopDef*
- assign each loop-invariant to temp. in loop header
- use temporary in loop body

Safety: loop-invariant expression may throw exception early

CS6013 - Jan 2020

Profitability:

- loop may execute 0 times
- Ioop-invariant may not be needed on every path through loop body

It is not as easy as it looks:

- : loop interchange? loop unrolling? loop fusion? Safety
- Opportunity : find memory-bound loop nests
- Profitability : machine dependent

Summary

- chance for large improvement
- answering the fundamentals is tough
- resulting code is ugly

Matrix-matrix multiply is everyone's favorite example

CS6013 - Jan 2020

(mostly)

V.Krishna Nandivada (IIT Madras)

Example: factoring loop invariants

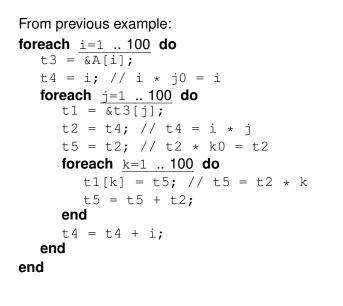

```
foreach i=1 .. 100 do
  // LoopDef = \{i, j, k, A\}
  foreach j=1 .. 100 do
     // LoopDef = \{j, k, A\}
     foreach k=1 .. 100 do
        // LoopDef = \{k, A\}
        A[i, j, k] = i * j * k;
     end
   end
end
```

- 3 million index operations
- 2 million multiplications

Example: factoring loop invariants (cont.)

Factoring the inner loop:	And the second loop:
foreach i=1 100 do	foreach $\underline{i=1}$ 100 do
// LoopDef = {i,j,k, A}	// LoopDef = $\{i, j, k, A\}$
foreach j=1 100 do	t3 = &A[i];
// LoopDef = $\{j, k, A\}$	foreach <u>j=1</u> 100 do
t1 = &A[i][j];	// LoopDef = $\{j, k, A\}$
t2 = i * j;	t1 = &t3[j];
foreach k=1 100 do	t2 = i * j ;
$// LoopDef = \{k, A\}$	foreach $\underline{k=1}$ 100 do
t1[k] = t * k;	// LoopDef = $\{k, A\}$
end	t1[k] = t * k;
end	end
end	end
end	
V.Krishna Nandivada (IIT Madras) CS6013	- Jan 2020 25 / 1

Example: strength reduction in loops

Strength reduction in loops

Loop induction variable: incremented on each iteration i₀, i₀ + 1, i₀ + 2, ...
Induction expression: ic₁ + c₂, where c₁, c₂ are loop invariant i₀c₁ + c₂, (i₀ + 1)c₁ + c₂, (i₀ + 2)c₁ + c₂, ...
replace ic₁ + c₂ by t in body of loop
insert t := i₀c₁ + c₂ before loop
insert t := t + c₁ at end of loop

CS6013 - Jan 2020

Contraction of the second

Example: strength reduction in loops

After copy propagation and exposing indexing: foreach i=1 ... 100 do t3 = A + (10000 * i) - 10000; t4 = i;foreach j=1 ... 100 do t1 = t3 + (100 * j) - 100; t5 = t4;foreach k=1 ... 100 do * (t1 + k - 1) = t5; t5 = t5 + t4;end t4 = t4 + i;end end

Example: strength reduction in loops

t1 = t7; t5 = t4;

foreach $k=1 \dots 100$ do

t5 = t5 + t4;

t8 = t8 + 1;

*t8 = t5;

t4 = t4 + i;

t6 = t6 + 10000;

t7 = t7 + 100;

t8 = t1;

end

end

end

Applying strength reduction to exposed index expressions: t6 = A;foreach i=1 .. 100 do t3 = t6; t4 = i;t7 = t3;foreach j=1 .. 100 do

Ordering optimization phases

- semantic analysis and intermediate code generation:
 - loop unrolling
 - inline expansion
- intermediate code generation:
 - build basic blocks with their Def and Kill sets
- build control flow graph:
 - perform initial data flow analyses
 - assume worst case for calls if no interproc. analysis
- early data-flow optimizations: constant/copy propagation (may expose dead code, changing flow graph, so iterate)
- OSE and live/dead variable analyses
- translate basic blocks to target code: local optimizations (register allocation/assignment, code selection)
- peephole optimization

V.Krishna Nandivada (IIT Madras)

CS6013 - Jan 2020

V.Krishna Nandivada (IIT Madras) CS6013 - Jan 2020 Again, copy propagation further improves the code.

Loop optimizations

- Loop unswitching
- Loop tiling
- Loop unrolling
- Loop reversal
- Loop-invariant code motion
- Loop inversion
- Loop interchange
- Loop fusion

- Loop distribution
- Strip mining
- Vectorisation (brief)

31/1
